

What is Container trying to solve?
It runs perfectly on my computer!

My computer

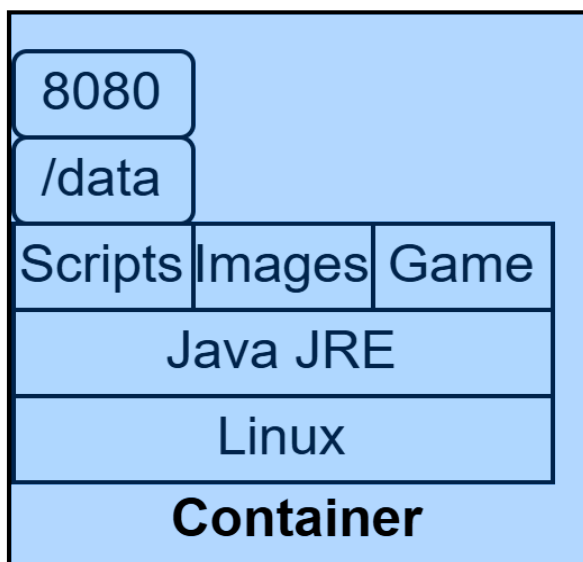

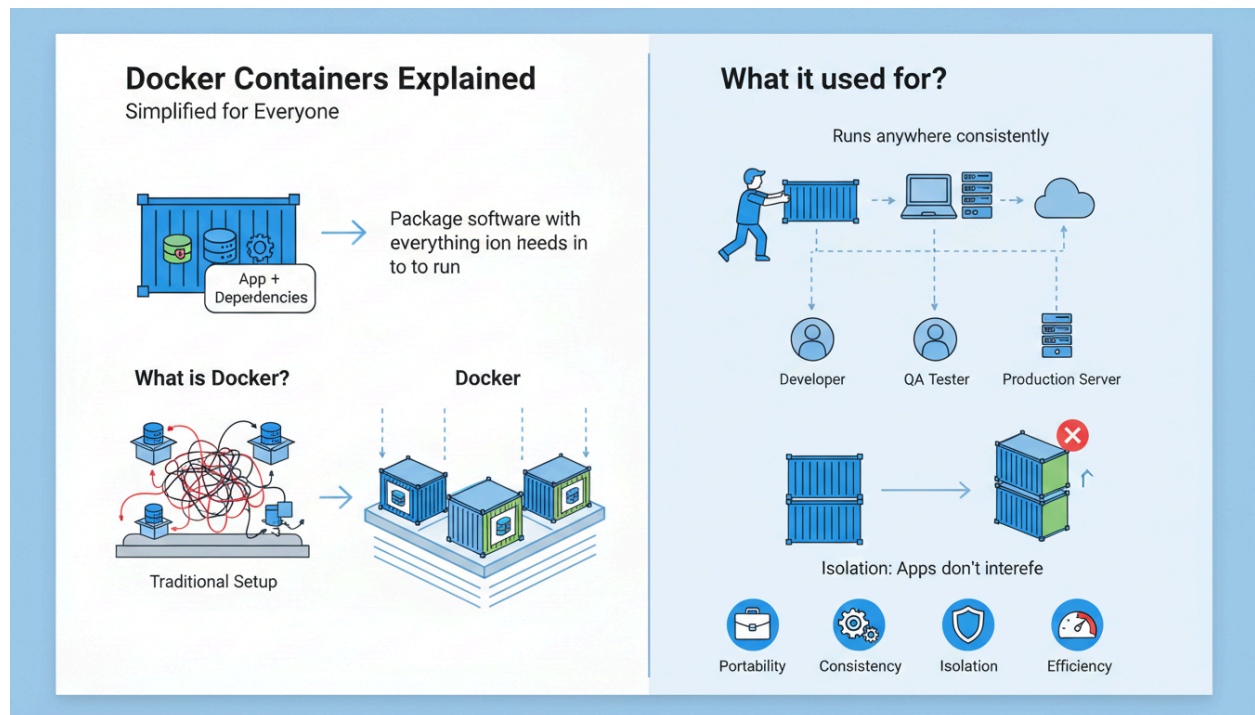

Your computer

Why?  becomes:

How does Container solve this?

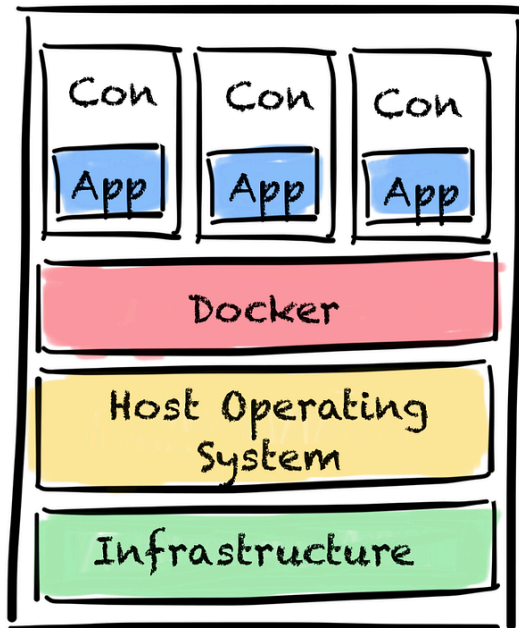

What is a Container?

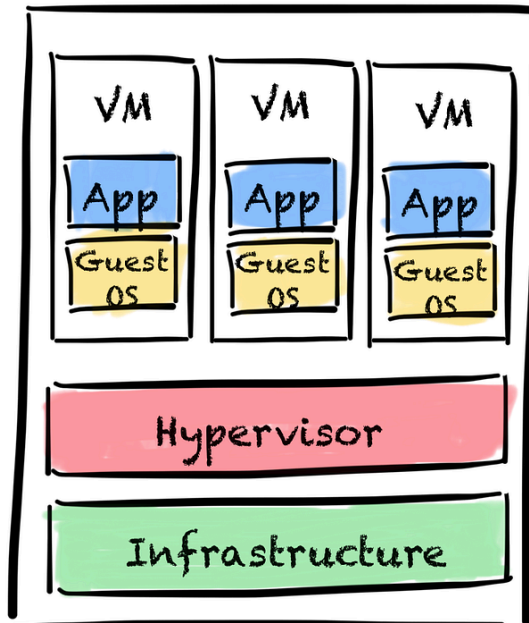

- A form of virtualisation
- Like Virtual Machine (VM) is a virtual aka simulated physical computer
- Container is a virtual Linux operating system

Container Architecture

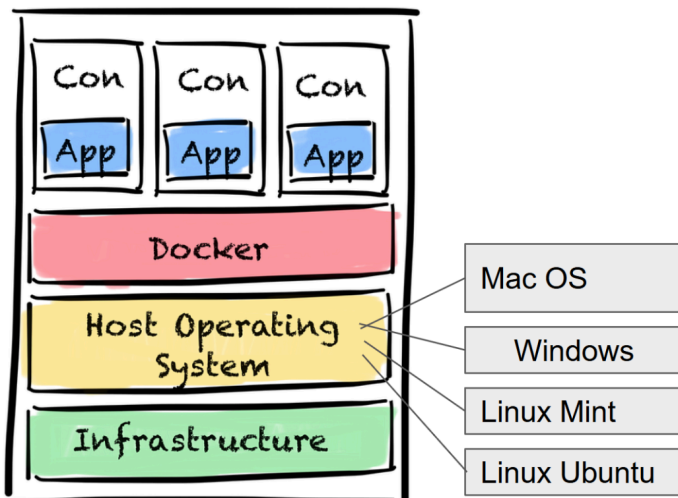

Container

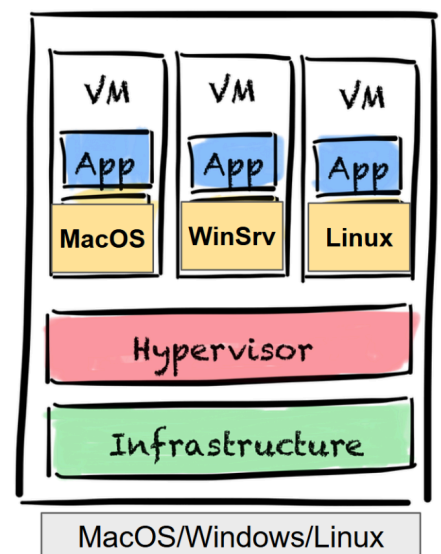

Virtual Machine

Container

Virtual Machine

Host Operating System can be Windows, MacOS, Linux Mint, Raspbian, RedHat Linux, Suse Linux, etc.

Docker Engine is an implementation of a Container Engine. Only one to work in Windows.
Other Container Engines are: Podman, LXC, containerd, CRI-O.

App installed -> may or may not uninstall cleanly
App in docker -> remove dockerised app, it deletes the entire thing.

Security -> can test app inside the docker container If it's a bad app with virus, etc, it stays inside the container (aka sandbox). It doesn't affect your machine.

All this is greatly simplified, and all these have exceptions that will break this rule.

Basic taxonomy in Docker
